With over 25 years of experience in the field of smart mobility, Serge has built up substantial experience in a diverse range of subdisciplines, including traffic flow theory, multi-modal traffic management, data collection, and AI.

The Transformative Role of AI in the Mobility domain

Prof. dr. Serge Hoogendoorn

08-05-2025

Not another AI talk!?

**A talk about what AI means for
mobility — and for us:
as students, academics, and
professionals...**

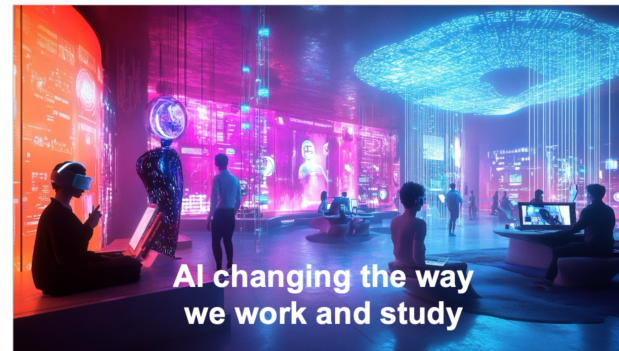

Transformative role of AI in the mobility domain?

AI could radically change the transportation system

Transforms our system

AI fundamentally **changes the system** that we are studying (understanding) and influencing

AI changing the way we work and study

Transforms 'us'

AI changes how we **study, do research and work** and what skills we need

**AI could radically change the
transportation system**

Two examples

Inclusive mobility

Supporting people living with disabilities in their daily travel

Efficient mobility

Making transportation services more efficient using AI

Inclusive mobility

Mobile Wayfinding:
A Solution for
Compare

A mobile wayfinding solution
patients seamlessly from
appointments, and follow
accommodating any pa
chosen travel modalities

89%

Of the people living with a disability
never use public transport

65%

Of the people living with a disability
indicate that they have difficulty
reaching a PT stop or station

AI to make mobility inclusive

Technology can
play an important role
to support people
with disabilities to
access transportation

Examples?
Dog and
MyEyes

Dr. Yan Feng
Assistant Professor

Efficient mobility

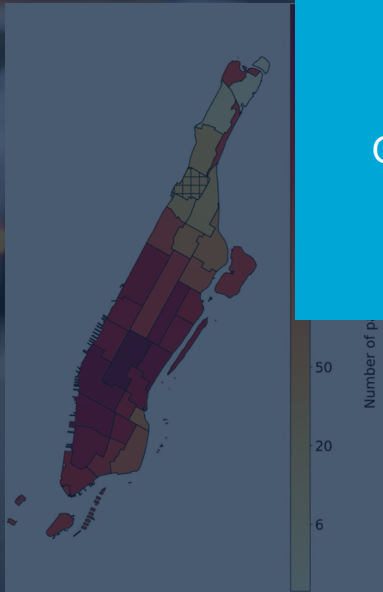

Elif Arslan
PhD candidate

~20%

Of the total trip time of a ride hailing service is spent on waiting

2-4 x

Higher impact of (perceived) waiting time compared to in-vehicle time for ride hailing services

AI to improve urban transport systems

ride hailing
ing travel

waiting
anhattan

ride-hailing
ndence on

private vehicles

- Other studies show reduction of deadheading miles by 80%

My 1st proposition

**The uptake of AI in the
TTE domain has been slow...**

... hampering solving many of the
societal challenges in traffic and transportation

Challenges AI in Traffic & Transport Engineering

Complexity and stochasticity

- **Traffic system complexity** ("butterfly effect": a small disruption can have a big effect), e.g. due to **non-linear nature** and emergent behaviour including **spontaneous phase transitions** (from free to congested flow)
- **Stochastic nature** and ill-predictability of the problem (stochastic behaviour, stochastic occurrence of events like incidents)
- Great influence of context (the one network is not the other, the one crowding event is not the other)
- Limited knowledge (understanding) of the (causal) effects of measures and interventions

Let's illustrate some of this issues by a case...

08-05-2025 11

A data-rich domain?

Is traffic and transportation data really that BIG? No!

- Data availability (including historical) is still limited, especially for **modes of transport other than the car** (e.g., pedestrians, bicycles)
- Data are **heterogeneous** (time and space scales), noisy and often biased
- Most **relevant situations** (high-risk situations, incidents, events, farmers' protests) are **rare** (and that is difficult for AI)

So this begs the question...

TU Delft

From trust to overreliance on AI?

- Distrust in AI relates to limited **understanding of how AI works**: how is advice is determined (transparency, explainability)?
- **Human autonomy in decision making**, aiming to prevent overreliance on automated systems and maintaining human oversight
- Risk of echo chambering for both humans and machines

These issues highlight the importance of explainable AI, but ever more so the role of training and education!

TU Delft

08-05-2025 29

Complexity

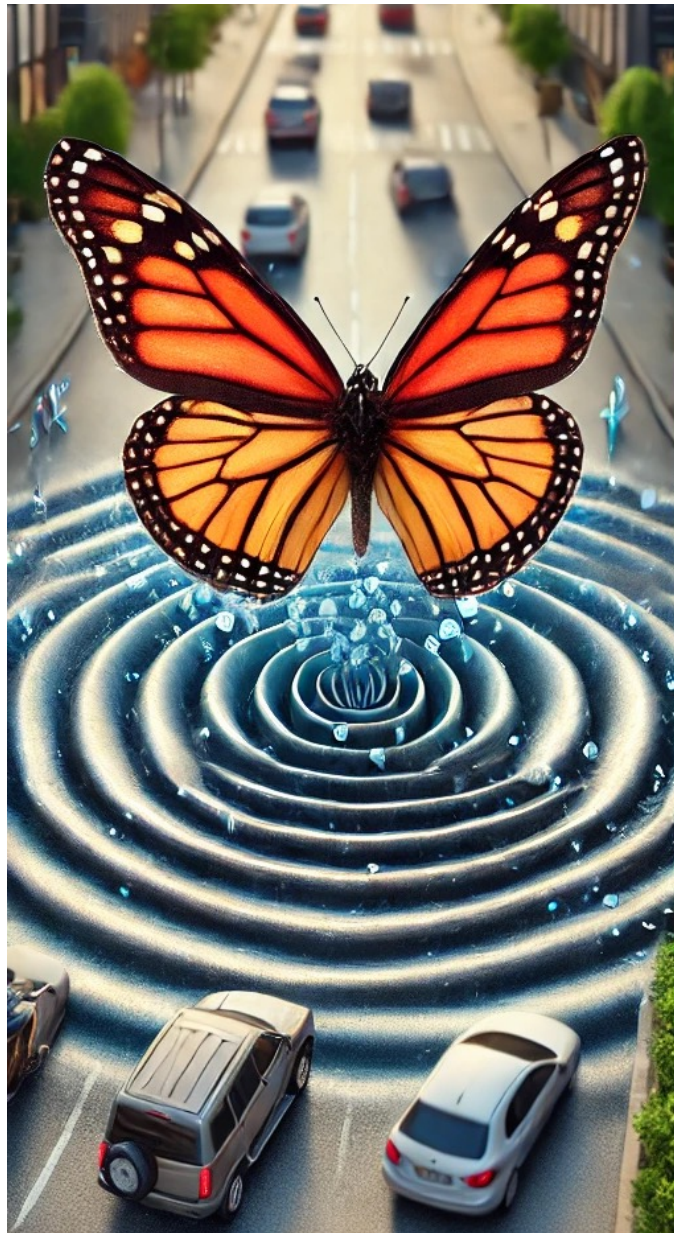

Traffic and transportation systems are complex and ill-predictable

Big data revolution?

Mobility data are often biased, erroneous, not representative, etc.

Role of ethics

Trust, human autonomy, transparency play major role in traffic and transportation

Complexity and stochasticity

- **Traffic system complexity** ("butterfly effect": a small disruption can have a big effect), e.g. due to **non-linear nature** and emergent behaviour including **spontaneous phase transitions** (from free to congested flow)
- **Stochastic nature** and ill-predictability of the problem (stochastic behaviour, stochastic occurrence of events like incidents)
- **Great influence of context** (the one network is not the other, the one crowding event is not the other)
- **Limited knowledge** (understanding) of the (causal) effects of measures and interventions

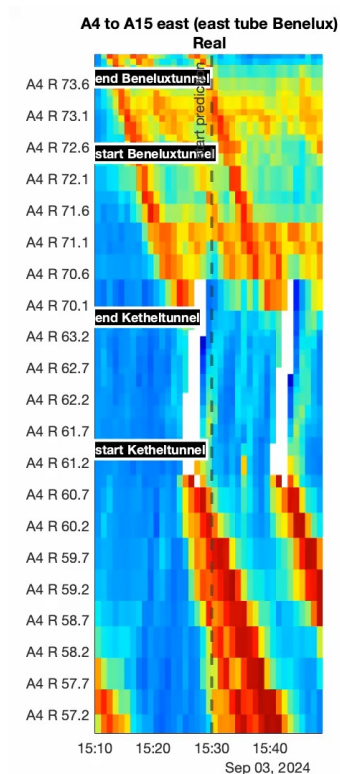

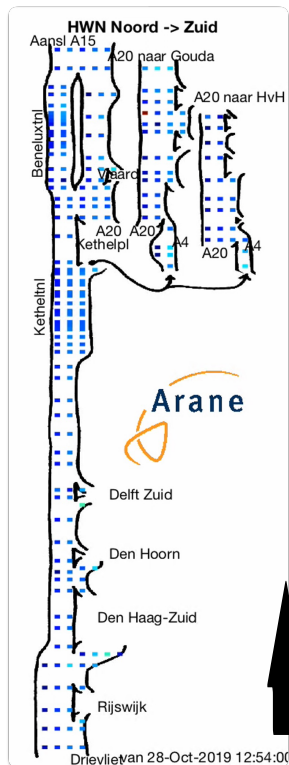

Let's illustrate some of this issues by a case...

To ensure traffic safety, **queuing in the Ketheltunnel has to be prevented**: when congestion spills back, the tunnel is closed based on current traffic situation.

When that occurs, queuing starts upstream of the tunnel substantially reducing the tunnel throughput due to the capacity drop phenomena.

Predicting short-term traffic conditions

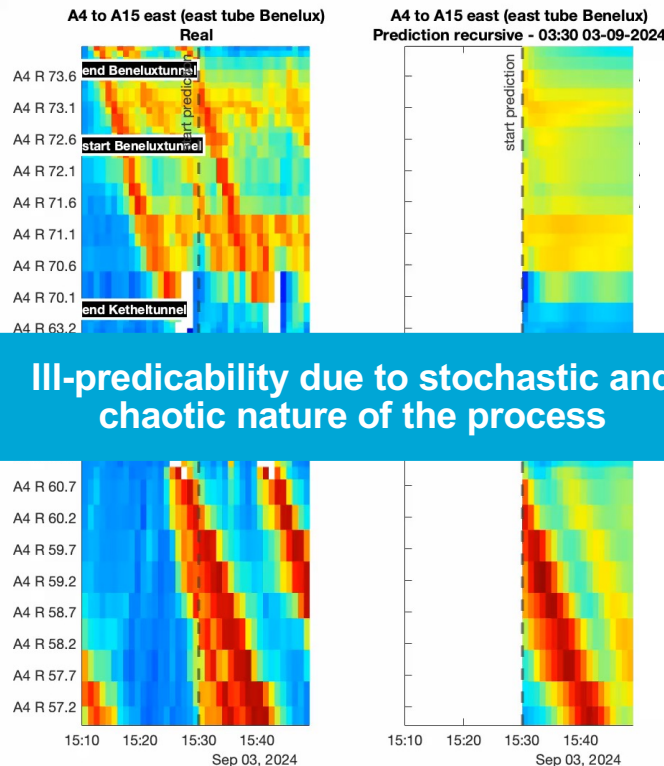

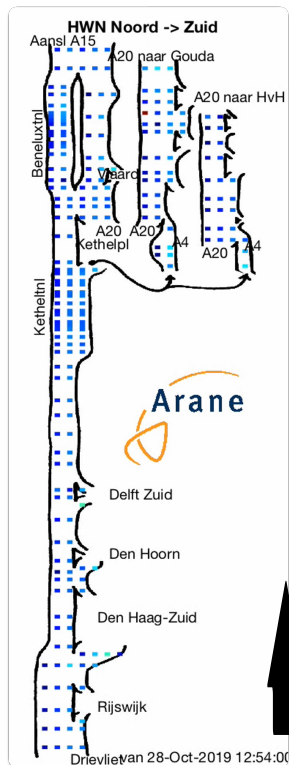

- Picture / animation provides overview of the loop observations in and around the tunnel
- **Speed contour plots** shows how:
 - high-density waves on freeway move in the downstream, direction through the tunnel
 - When the queue reaches the tunnel, the tunnel is temporarily closed, and the queue is moved to the upstream entry of the tunnel

Research objective?

- Test **multi-step Deep Learning method** for short-term prediction (30 min ahead) for network wide traffic management purposes where we focus on preventing the tunnel metering to activate

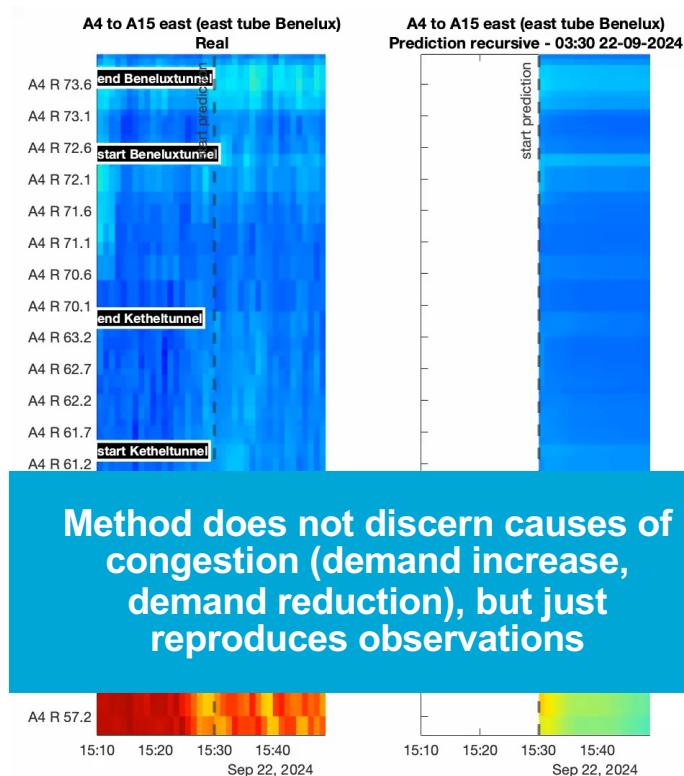

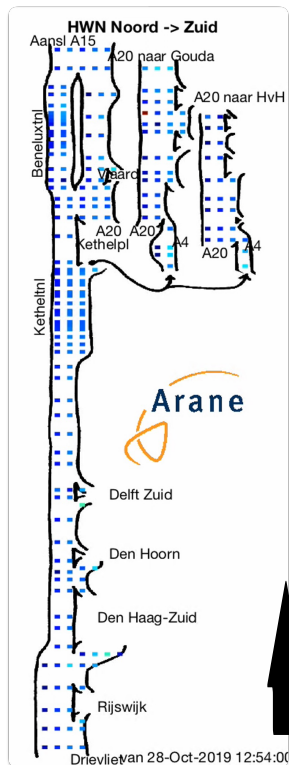

Predicting short-term traffic conditions

III-predicability due to stochastic and chaotic nature of the process

- Animation shows development of 30 minute ahead predictions
- Deep Learning model **succeeds** in picking up general traffic operations patterns (e.g., shockwave propagation) but **fails** on several aspects:
 - Start of congestion is often missed (initiation of the shockwave)
 - Situations that show change in demand (e.g., weekend) or supply conditions (e.g., roadworks) are not reproduced
- **Limitations impact applicability!**

Predicting short-term traffic conditions

- Animation shows development of 30 minute ahead predictions
- Deep Learning model **succeeds in** picking up general traffic operations patterns (e.g., shockwave propagation) but **fails** on several aspects
 - Start of congestion is often missed (initiation of the shockwave)
 - Situations that show change in demand (e.g., weekend) or supply conditions (e.g., roadworks) are not reproduced
- **Limitations impact applicability!**

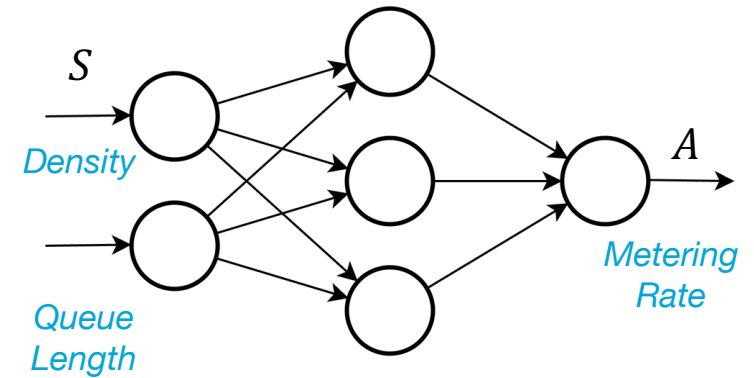

My 2nd proposition:

In Traffic and Transportation Engineering, application of AI requires proper integration of data science and domain knowledge

Two examples...

Deep Reinforcement Learning

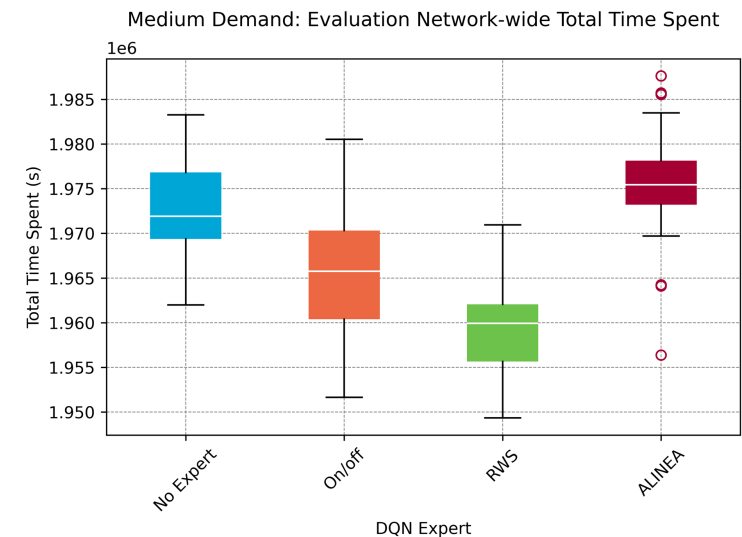

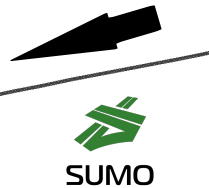

- DRL has been proposed as a powerful AI method for a variety of control tasks including **ramp-metering**, but has yet to prove their value idue to very slow tuning
- Objective: include **expert (= domain) knowledge** (i.c., existing control methods, such as ALINEA or RWS) by pre-training: speeds up tuning and improves performance (see picture)
- Current work looks at how **expert knowledge** can be included for network coordination

Callum Evans
PhD Candidate

Ramp meter

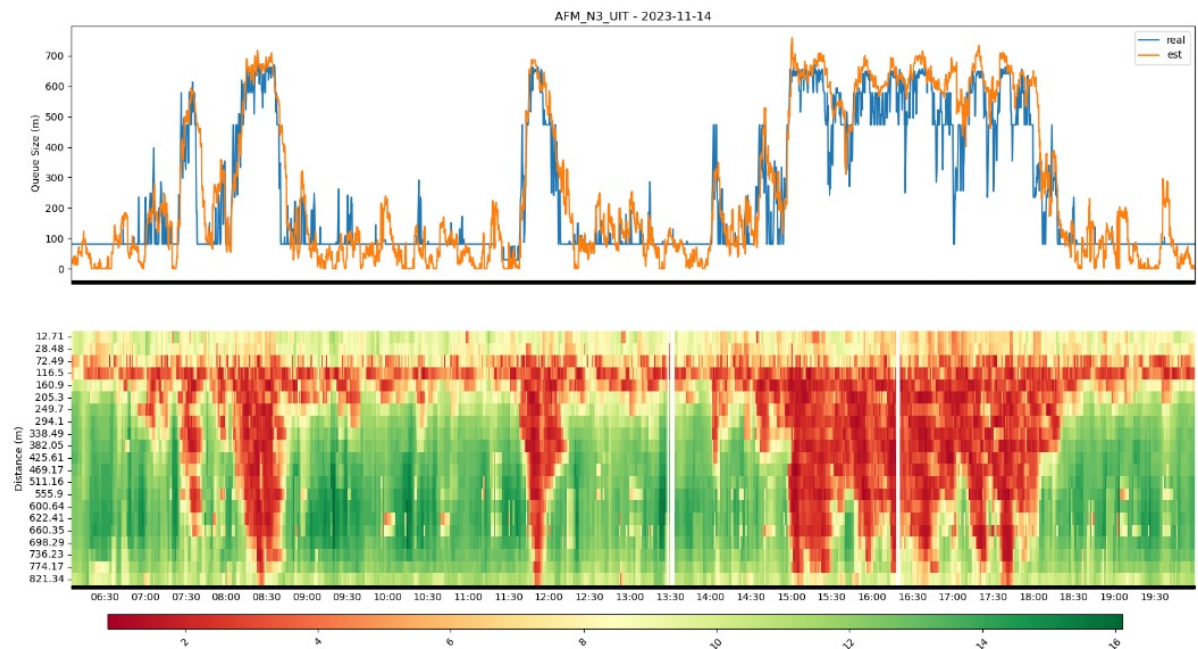

Queue estimation for real-time traffic control

- Notoriously difficult problem in traffic engineering as queues **cannot be directly observed**
- Real-time queue lengths are needed for many control algorithms (e.g, Max Pressure for queue balancing; ALINEA and RWS for queue protection)
- Recent work focusses on **AI-supported Kalman filters**, effectively combining traffic flow models with powerful AI
- Example application Rotterdam

Ting Gao
PhD Candidate

Challenges of applying AI in traffic & transport?

Complexity and stochasticity

- **Traffic system complexity** ("butterfly effect": a small disruption can have a big effect), e.g. due to **non-linear nature** and emergent behaviour including **spontaneous phase transitions** (from free to congested flow)
- **Stochastic nature** and ill-predictability of the problem (stochastic behaviour, stochastic occurrence of events like incidents)
- Great influence of context (the one network is not the other, the one crowding event is not the other)
- Limited knowledge (understanding) of the (causal) effects of measures and interventions

Let's illustrate some of this issues by a case...

Complexity

Traffic and transportation systems are complex and ill-predictable

Big data revolution?

Mobility data are often biased, erroneous, not representative, etc.

Ethics

Trust, human autonomy, transparency play major role in traffic and transportation

A data-rich domain?

Is traffic and transportation data really that **BIG**? No!

- Data availability (including historical) is still limited, especially for **modes of transport other than the car** (e.g., pedestrians, bicycles)
- **Data are heterogeneous** (time and space scales), noisy and often biased
- Most **relevant situations** (high-risk situations, incidents, events, farmers' protests) **are rare** (and that is difficult for AI)

So this begs the question...

**Can AI make a “silk purse
out of a sow’s ear”?**

The **Crowd Safety Manager** is a decision support platform for crowd managers that brings together and visualises relevant sources of data, combines these data (**data fusion**), predicts crowding conditions (**prediction and forecasting**) and assesses risk

Op initiatief van

Den Haag

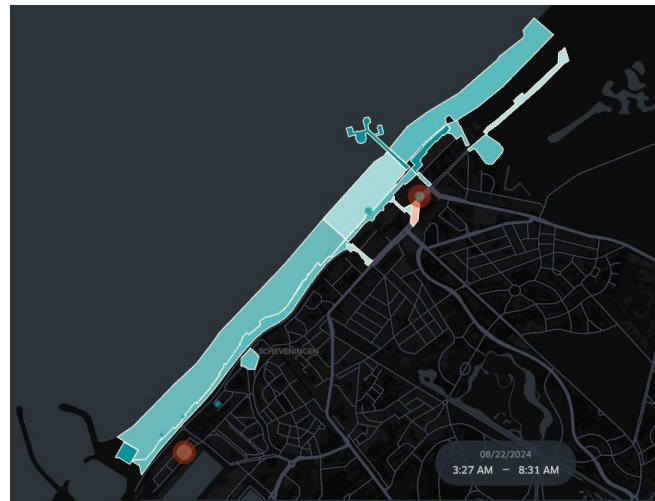

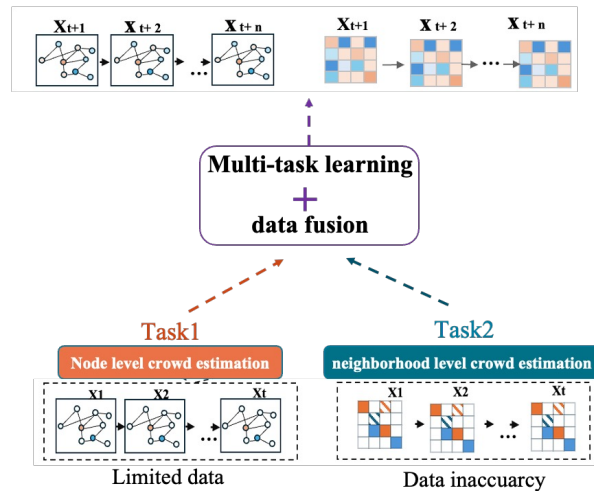

CSM and AI

- For the **Crowd Safety Manager (CSM)**, **none** of the available datasources provides a comprehensive or accurate picture of crowding:
 - **Resono data** stems from smartphones: available everywhere, but biased + low granularity (spatial)
 - **Cameras** provide density, speed, flow: low bias, accurate, but local and sparse
 - **GooglePOI data**: available at many locations, low temporal granularity (1 hour resolution)
- Key challenges?
 - Can AI be used to improve our data (remove bias, increase accuracy)?
 - Can we predict high risk situations reliably?

Data fusion by multi-task machine learning

Test use of AI for data fusion to remove bias and improve spatial and temporal granularity:

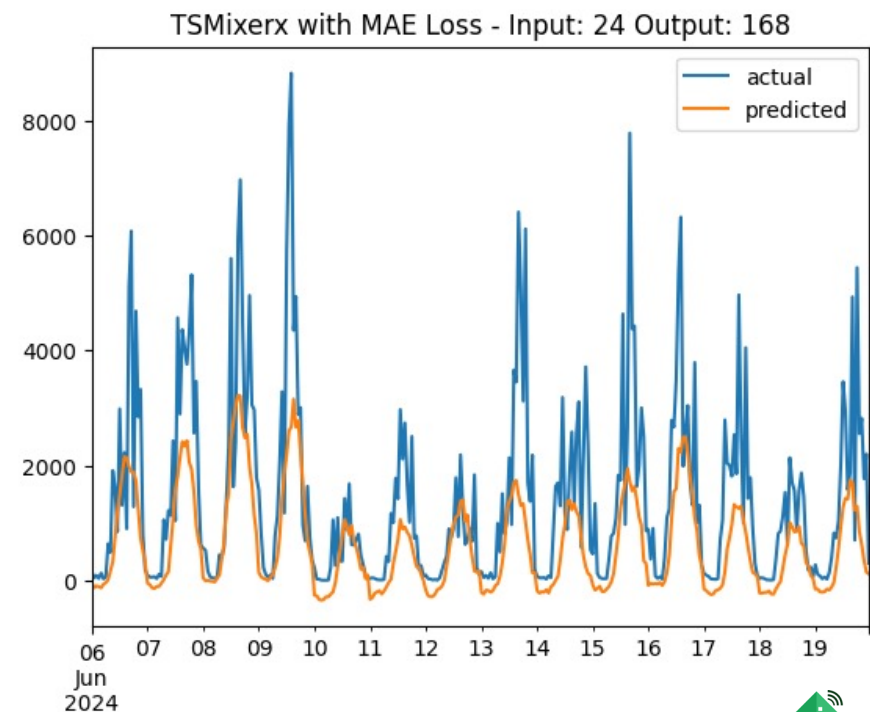

- Animation shows unbiased crowdedness levels on a region level at various locations
- Hourly Google POI data has been further disaggregated to 5 min level by capitalising on temporal resolution of region data sources (Resono)

Yanyan Xu
PhD Candidate

Impact of non-representative data

- Aim to predict crowdedness several days ahead to support **planning** and **real-time crowd management**
- Deep Learning methods seem suitable for this task, yet application of 'off the shelf' AI technology does not result in useful outcomes: **peaks are structurally underestimated**
- **What is the main issue?**
 - Data contains mostly information on situations that are not crowded, nor risky
 - Training ML methods using these data provides predictions that are on average good, but do not reflect peaks well

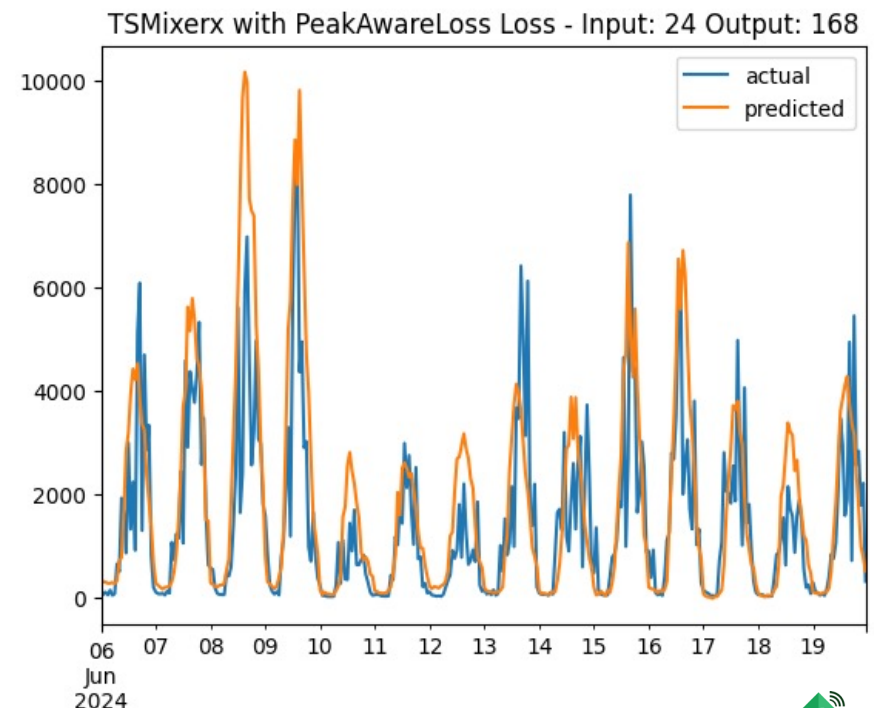

Non-representative data and prediction impact

- Define new **loss function** that allow for appropriate prediction of **peak hours** and **peak days**:
 - Higher weights for peak periods ('peak boost')
 - Penalize underprediction to reduce the chance that we predict too small crowds and arrange for too few support staff

Theivaprakasham Hari
PhD Candidate

Future steps CSM

- Five year project AICOMPASS sponsored by NWO
- AI providing **information** to crowd managers and planners about **risk**
- AI providing **optimized advice** to the crowd managers and planners (what to do?)
- See AI as a member of a **hybrid team of humans and machines**: what the key issues involved?

Challenges of applying AI in traffic & transport?

Complexity and stochasticity

Transformative role of AI in the mobility domain?

AI could radically change the transportation system

Transforms our system

AI fundamentally **changes the system** that we are studying

AI changing the way we work and study

Transforms 'us'

AI changes how we **study, do research and work** and what skills we need

A futuristic digital environment where people interact with large-scale projections and VR. The scene is dimly lit, with vibrant red and blue light emanating from the digital displays. On the left, a person wearing a VR headset sits on a low platform, gesturing towards a large wall of red digital data. In the center, a person stands before a large projection of a human figure. To the right, another person sits on a low platform, looking at a large screen displaying a 3D model. In the background, several other people are visible, some sitting at circular tables with screens, others standing and looking at the large wall projections. The ceiling is a complex, glowing blue structure with many vertical lines. The overall atmosphere is one of high-tech, immersive digital interaction.

**AI changing the way
we work and study**

AI transforms how we work...

- AICOMPASS looks at the **future role** of AI in a 'human – machine' teams
- But AI is already changing the way we work (and study!) **now**:
 - Performs simple office tasks, does our reporting
 - Provides us with better information, catered to our needs
 - Support planning, design, and optimisation tasks
 - Eventually provides complex decision support

TTE engineers (need to) change!

The future Traffic and Transport Engineer needs complementary skills (technical and soft):

- In 2023, 65% of transport/logistics employers said digital skills outweigh formal degrees
- By 2030, a **global shortage of 250,000+ AI-skilled professionals** in mobility is expected
- Projections for the US show that 44% of tasks are automatable; but **only 12% of transport planning jobs may disappear** as roles shift

Will we be obsolete?

Well, there are some counterarguments:

- **Model collapse:** AI being trained by AI generated data eventually results in plateau
- **Impact of domain knowledge** in understanding and improving AI
- AI (still?) seems to lack creativity

Next to human autonomy, several other risks can be identified (loss of system understanding, reinforcement bias, and automation lock-in) if humans become complacent...

My final proposition:

**As long as ChatGPT is not able to
tell a decent joke, we are okay!**
